

SQL AGGREGATE FUNCTIONS

An SQL aggregate function calculates on a set of values and returns a single value. For example, the average function (AVG) takes a list of values and returns the average.

The following are the commonly used SQL aggregate functions:

- **AVG**– returns the average of a set.
- **COUNT**– returns the number of items in a set.
- **MAX** – returns the maximum value in a set.
- **MIN** – returns the minimum value in a set
- **SUM** – returns the sum of all or distinct values in a set

Except for the **COUNT** function, SQL aggregate functions ignore null. You can use aggregate functions as expressions only in the following:

- ✓ **AVG**- returns the average values in a set.

```
SELECT ROUND(AVG(salary), 0) avg_salary FROM employees
```

- ✓ **MIN**- returns the minimum value of a set.

```
SELECT MIN(salary) min_salary FROM employees
```

- ✓ **MAX**- returns the maximum value of a set.

```
SELECT MAX(salary) highest_salary FROM employees
```

- ✓ **COUNT**- returns the number of items in a set.

```
SELECT COUNT(*) headcount FROM employees
```

- ✓ **SUM**- returns the sum of all values.

```
SELECT SUM(salary) FROM employees
```
